## Introduction to R for data analysis

#### Peter Carbonetto

Research Computing Center and the Dept. of Human Genetics University of Chicago

## Aims of workshop

- **1.** Work through a basic data analysis in R.
- 2. Understand how to import data from a CSV file into an R data frame.
- **3.** Use standard tools to summarize & manipulate data frames.
- 4. Learn how to install & use R packages.
- **5.** Use ggplot2 to create plots from data frames.
- 6. Learn through "live coding"—this includes learning from our mistakes!

## Our goal: Analyze Divvy data from 2016 & 2017

- Investigate bike sharing trends in Chicago.
- We will use data made available from Divvy:
  - www.divvybikes.com/system-data
- Much of the effort will be spent importing the data, inspecting the data, and preparing the data for analysis.
- Once we have carefully prepared the data, creating visualizations is (relatively) easy.

## It's your choice

Your may choose to...

- Use R on your laptop.
- Use RStudio on your laptop.
- Use R or RStudio (Desktop or Server) on the RCC cluster.
- Pair up with your neighbour.
- Follow what I do on the projector.

**Note:** If you use the RCC cluster I'm assuming you know how to set up an interactive computing session with appropriate amount of time and memory, load R or RStudio, and display graphics (e.g., using ThinLinc).

## Software we will use today

- 1. R
- 2. R packages readr, ggplot2 & cowplot.
- 3. RStudio (optional).

**Note:** I'm assuming you have already installed R and/or RStudio on your laptop, or you are using the RCC cluster.

## **Outline of workshop**

- 1. Initial setup.
- 2. Load & prepare the Divvy station data.
- 3. Load & prepare the Divvy trip data.
- 4. Create a map of the Divvy stations.
- **5.** Create plots comparing bike sharing in 2016 & 2017.

## **Initial setup**

- WiFi
- Power outlets
- Pace, questions (e.g., keyboard shortcuts).
- Help.

## Download or "clone" git repository

Download the workshop packet to your computer.

- Go to: github.com/rcc-uchicago/R-intro-divvy-2
- To download, click the green "Clone or download" button.

Or, if you have git, run this command:

```
git clone https://github.com/rcc-uchicago/
R-intro-divvy-2.git
```

(Note the URL in the git command should not contain any spaces.)

 Note: If you are using the RCC cluster, also download workshop packet on the cluster.

## What's in the workshop packet

```
R-intro-divvy-2
  /analysis # Scripts implementing data analyses.
  /code # Additional code used in analyses.
  /data # Original ("raw") data.
  /docs # Additional workshop materials.
  /output # Processed data & results files.
```

 This setup mimics how I typically organize the code, data and results for my projects.

## Open the slides on your computer

- This PDF is useful for copying & pasting code from the slides.
- The PDF is in the "docs" folder of the workshop packet.
- You can also view the PDF by clicking the "docs" item in the file listing on the GitHub webpage.

## Set up your R environment

- Launch R or RStudio.
- We will run all the code from the "analysis" folder.
- To change your working directory:
  - ▷ In R, use setwd() function.
  - ▷ In RStudio, select Session > Set Working Directory > Choose Directory…

Before continuing, check that you have the right working directory:

```
getwd() # Should end with "analysis".
```

#### Run sessionInfo()

Check the version of R that you are using:

```
sessionInfo()
```

If you are using an older version of R (version 3.3 or earlier), I strongly recommend upgrading to the latest version. Some of the examples may not work in older versions of R.

## Check your R environment

The R environment is where all variables and functions are stored and accessed. You should start with an empty environment. Check this:

```
ls()
```

If you see names of objects listed, it means your environment is not empty, and you should restart R with a clean environment.

- Do rm(list = ls()).
- Or, in RStudio, go to Session > Restart R.

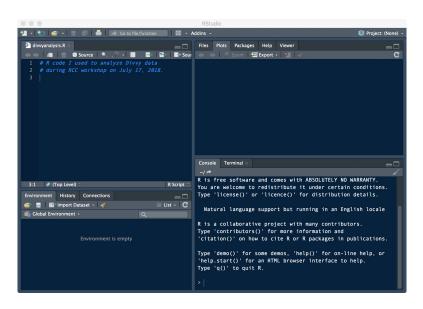

# Create a file to keep track of your analysis code

- In RStudio, select File > R Script.
- Alternatively, use your favourite editor (nano, emacs, vim, Atom, etc).
- Add some comments to the title to remind yourself what this file is for, e.g.,

```
# Some of the R code I wrote during the RCC
# workshop on July 17, 2018.
```

• Save the file in the "analysis" folder. Name the file whatever you'd like (e.g., divvyanalysis.R).

#### The console is the "brains" of RStudio

## **Download the Divvy data**

- Disk space required: at least 2 GB.
- Download the 2016 & 2017 data files from here:
- Download them to the "data" folder.
- You should have 4 ZIP files:

```
Divvy_Trips_2016_Q1Q2.zip
Divvy_Trips_2016_Q3Q4.zip
Divvy_Trips_2017_Q1Q2.zip
Divvy_Trips_2017_Q3Q4.zip
```

Decompress ("unzip") all of these files.

## Check that you have all the files

After unzipping, you should have 15 CSV files.

```
Sys.glob("../data/*.csv")
```

If you don't see all 15 CSV files, you have not successfully downloaded and/or unzipped all the files in the "data" directory.

## **Outline of workshop**

- 1. Initial setup.
- 2. Load & prepare the Divvy station data.
- 3. Load & prepare the Divvy trip data.
- 4. Create a map of the Divvy stations.
- **5.** Create plots comparing bike sharing in 2016 & 2017.

#### Import the station data into R

Load the most recent station data into an R "data frame":

This will define a new object, "stations", in your environment:

```
ls()
```

It is a "data frame" object:

```
class(stations)
```

What does "read.csv" do, and what is a "data frame"? R has detailed documentation:

```
help(read.csv)
help(data.frame)
```

## Inspect the station data

Run these commands to start inspecting the station data:

```
nrow(stations)
ncol(stations)
head(stations)
tail(stations)
summary(stations)
```

Inspect the data in more detail:

```
sapply(stations, class)
print(object.size(stations), units = "Kb")
```

What do we learn about the station data from running these commands? Does this reveal any issues with the data?

## Take a closer look at the "dpcapacity" column

Create a new object containing only the "dpcapacity" column:

```
x <- stations$dpcapacity
```

Run these commands to take a closer look at the "dpcapacity" column:

```
class(x)
length(x)
summary(x)
table(x)
```

Did we gain any additional insight from running these commands?

## Take an even closer look at "dpcapacity"

It is interesting that a few of the Divvy bike stations are much larger than the others, whereas others have no docks. Where are these stations?

```
subset (stations, dpcapacity == 0)
subset (stations, dpcapacity >= 40)
```

Alternatively, we can sort the table rows, then inspect the top and bottom rows:

```
rows <- order(stations$dpcapacity, decreasing=TRUE)
stations <- stations[rows,]
head(stations)
tail(stations)</pre>
```

What was risky about line 2?

## Take a closer look at the "city" column

Above we inspected *numeric* data. Next's, let's look at an example of non-numeric data.

```
x <- stations$city
class(x)
summary(x)</pre>
```

The summary is not very useful here! The key is to convert to a "factor" (factor = categorical variable):

```
x <- factor(stations$city)
class(x)
summary(x)</pre>
```

Did you discover an issue with the data from running these commands?

#### What is a "factor"?

Factors are very useful. Let's take a deeper look.

```
attributes(x)
unclass(x)
```

## Improving the "city" column

Let's fix the problem we found earlier. First, select the offending rows of the table:

```
rows <- which(stations$city == "Chicago ")
```

Fix the "city" entry for the selected rows:

```
stations[rows,"city"] <- "Chicago"
```

The "city" column is more useful if it is a factor, so let's convert it:

## There are many ways to select rows & columns

Select first 4 rows of "name" column:

```
stations$name[1:4]
stations[1:4,2]
stations[1:4,"name"]
```

• Do you prefer one approach?

Select first 4 rows and multiple columns:

```
stations[1:4,c(2,3,6)]
stations[1:4,c("name","city","dpcapacity")]
```

Can rows be selected by name?

```
colnames (stations)
rownames (stations)
```

#### Save your code & session state

It is important to periodically save:

- 1. your code,
- 2. the state of your R environment.

To save your environment, do something like this:

```
save.image("../output/divvyanalysis.RData")
```

Later, to restore your environment in a new session, run load("../output/divvyanalysis.RData").

## Main concepts covered so far

- The R environment & working directory.
- Read a data frame from a text (CSV) file.
- Tools to inspect a data frame.
- Manipulate a data frame.
- Factors = categorical variables.
- Selecting & and columns.
- Order rows of a data frame.
- Save state of R environment.

## **Outline of workshop**

- 1. Initial setup.
- **2.** Load and prepare the Divvy station data.
- 3. Load and prepare the Divvy trip data.
- 4. Create a map of the Divvy stations.
- **5.** Create a scatterplot comparing bike sharing activity in 2016 and 2017.

#### Import the Divvy trip data into R

Previously, we used read.csv to import station data into R. Let's now use the same function to load the most recent trip data:

You may find that this command look longer to run than before. Consider that the trips data is much larger:

```
nrow(trips)
ncol(trips)
```

This gives an opportunity to demonstrate faster methods for importing large data sets.

## Import Divvy trip data using readr (optional)

Install the readr package from CRAN:

```
install.packages("readr")
```

Load the functions from the package into your R environment:

```
library(readr)
```

Let's use the read\_csv function from this package:

How much faster is read\_csv?

• Note: The na = "NA" argument was added to reproduce behaviour of read.csv.

## Import Divvy trip data using readr (optional)

The read\_csv output is not a data frame—it is a "tibble".

```
class(trips)
```

Typically, I convert it to a data frame:

```
class(trips) <- "data.frame"</pre>
```

• For more on tibbles, see:

```
    http://r4ds.had.co.nz
```

- The readr package has many other features not covered here.
- Another fast method is fread from the data.table package.

## More on packages in R

"Vignettes" are a great way to learn about a package:

```
vignette(package = "readr")
vignette("readr")
```

CRAN is the official package source:

```
    https://cran.r-project.org.
```

- Other good places to find packages:
  - ⊳ Bioconductor
  - GitHub.
- What packages are already installed?
   rownames (installed.packages ())
- Where do the packages live? .libPaths()
- How to learn more about a package?
   help (package=readr)

## A first glance at the trips data

Let's use some of the same commands we used earlier to quickly get an overview of the trip data:

```
nrow(trips)
ncol(trips)
head(trips)
summary(trips)
```

Unfortunately, the summary command isn't particularly informative for many of the columns.

What columns should we convert to factors?

## Convert "gender" to a factor

Let's start by converting the "gender" column to a factor:

```
trips <- transform(trips,gender = factor(gender))
summary(trips$gender)
levels(trips$gender)</pre>
```

What problem have we stumbled upon?

## Handling "missing" data

In R, "missing data" should always be assigned the special value NA ("not available" or "not assigned"):

Many functions in R will correctly handle missing data as long as they are encoded as  ${\tt NA}.$ 

 Note: read\_csv automatically converts empty character strings to NA, but read.csv does not.

#### Convert "station" columns to factors

Next, let's convert the "from station" and "to station" columns to factors:

```
trips <- transform(trips,
  from_station_name = factor(from_station_name),
  to_station_name = factor(to_station_name))
summary(trips)</pre>
```

The summary is now more informative. However, here it is better to specify the "levels" when converting to factors:

```
x <- stations$name
trips <- transform(trips,
  from_station_name = factor(from_station_name, x),
  to_station_name = factor(to_station_name, x))</pre>
```

Why is this important?

# **Example: summarizing trips by station (optional)**

Create a new data frame containing the "from" and "to" trip totals:

With this new data frame, we can easily create a scatterplot comparing the rate of departures to arrivals at each station:

Exercise: Use subset to find the one station that has many more departures than arrivals.

#### A note about dates & times

- summary (trips) is also not useful for the dates & times.
- Processing dates & times is more complicated.
- See help(strptime) and the lubridate package.

# Main concepts covered in second part

- Install & use a package.
- Handle missing data (NA's).
- Create a data frame.
- Create a plot from a data frame.

# Preparing data is tedious

Data preparation is sometimes >90% of the effort!

• Many analysis mistakes are due to poor data preparation.

#### Common issues include:

- Formatting mistakes in CSV file.
- Converting table columns to the appropriate data type.
- Entry inconsistencies (e.g., additional spaces).
- Missing data.
- Many other examples of Poor Practices in recording data.

(And we haven't yet dealt with merging data from multiple files—this usually creates more headaches!)

## Moving beyond data preparation

- So far, we have illustrated a few of the challenges of working with large tabular data sets ("data frames").
- In order to proceed to fun stuff, I've "hidden" some of the additional complications—I wrote a function in R to import and merge all the Divvy data into a single data frame.

## **Outline of workshop**

- 1. Initial setup.
- 2. Load & prepare the Divvy station data.
- 3. Load & prepare the Divvy trip data.
- 4. Create a map of the Divvy stations.
- **5.** Create plots comparing bike sharing in 2016 & 2017.

## Import the 2016 & 2017 Divvy data

I wrote a function read.divvy.data to automate the reading and processing of the Divvy data: it reads all the CSV files, then merge them into two data frames: one for the stations, and one for the trips.

```
source("../code/functions.R")
ls()
```

Choose which station and trip files to import.

```
tripfiles <- Sys.glob("../data/Divvy_Trips*.csv")
stnfile <- "../data/Divvy_Stations_2017_Q3Q4.csv"</pre>
```

#### Import the 2016 & 2017 Divvy data

This may take a minute to run, or longer if you have not installed the readr package.

```
divvy <- read.divvy.data(stnfile,tripfiles)</pre>
```

The output is a "list" containing two data frames:

```
names(divvy)
stations <- divvy$stations
trips <- divvy$trips
rm(divvy)
head(stations)
head(trips)
nrow(trips)
print(object.size(trips), units = "Gb")</pre>
```

- Were more trips taken in 2016 or 2017?
- Which columns were converted to factors?

# Out first ggplot: a map of the Divvy stations

We will use the **ggplot2** package. It is a powerful (though not always intuitive) set of plotting functions that extend the base plotting fuctions in R.

```
install.packages("ggplot2")
```

I also recommend the **cowplot** package, an extension to ggplot2 developed by Claus Wilke at UT Austin.

```
install.packages("cowplot")
```

Load the ggplot2 and cowplot functions:

```
library(ggplot2)
library(cowplot)
```

#### Plot station longitude vs. latitude

The "stations" data frame gives the geographic co-ordinates (latitude & longitude) for each station. With ggplot, we can create a station map from the "stations" data frame in only a few lines of code:

## Adjusting the plot

Let's make a few small adjustments to improve the plot:

What geographic features of Chicago are recognizable from this plot?

# Scale stations by the number of departures

Next, let's add an additional piece of information to this visualization:

• Number of departures at each station, should (?) roughly correspond to population density.

To do this, we need to add a new column to the "stations" data frame containing the total number departures, which is calculated from the "trips" data frame:

```
counts <- table(trips$from_station_id)</pre>
```

The counts should be the same order as the stations—why is this?

```
all(names(counts) == stations$id)
```

## Scale stations by the number of departures

Add these trip counts to the "stations" data frame:

```
stations$departures <- c(counts)
head(stations)</pre>
```

Let's use this column in our new plot:

#### How to save and share your plot

For exploratory analyses, GIF and PNG are great formats because the files are easy to attach to emails or webpages:

```
ggsave("../output/station_map.png",
    plot = p, dpi = 150)
```

For print or publication, save in a vector graphics format:

```
ggsave("../output/station_map.pdf",plot = p)
```

## Save your code & session state

This is a good time to save your session.

```
save.image("../output/divvyanalysis.RData")
```

#### Compare 2017 biking activity against 2016

Earlier, we observed an increase in trips from 2016 to 2017. Which stations experienced the largest increase?

- To examine this, we need to count trips separately for 2016 and 2017.
- Then we add these counts to the "stations" data frame.

We will use the subset and table to do this:

```
d1 <- subset(trips, start.year == 2016)
d2 <- subset(trips, start.year == 2017)
x1 <- table(d1$from_station_id)
x2 <- table(d2$from_station_id)
stations$dep.2016 <- c(x1)
stations$dep.2017 <- c(x2)
head(stations)</pre>
```

#### Scatterplot of trips by station (2016 vs. 2017)

As before, now that we have prepared a data frame, plotting with ggplot is relatively straightforward:

It is difficult to tell which stations had more trips in 2017—we need to compare against the x = y line.

One station stands out because it has had a much larger increase in trips than other stations. Where is this station?

## Save your code & session state

Save your final results for safekeeping.

```
save.image("../output/divvyanalysis.RData")
```

#### ggplot: Take home points

- Creating sophisticated plots requires relatively little effort provided the data are in the right form.
- All plots in ggplot have these three elements:
  - 1. A data frame.
  - 2. An "aesthetic mapping" that declares how columns are plotted.
  - **3.** A "geom", short for "geometric object," that specifies the type of plot.
- Plots are created by combining "layers" using the + operator.

# Why data analysis in R?

- In R, a spreadsheet ("data frame") is an object that can be inspected, manipulated and summarized with code.
- Therefore, we can write scripts to automate our data analyses.

## **Parting thoughts**

- Always record your analysis steps in a file so you can reproduce them later.
- 2. Keep track of which packages (and the versions) you used with sessionInfo().
- 3. Use packages—don't reinvent the wheel.
- **4.** Email help@rcc.uchicago.edu for advice on using R on the RCC cluster.
- 5. Use "R Markdown" to document your analyses.
- See the workflowr package for simplifying organizing & sharing of data analyses; e.g., stephenslab.github.io/wflow-divvy.
- 7. Thank you!
