Introduction to R for data analysis

Peter Carbonetto

Research Computing Center and the Dept. of Human Genetics University of Chicago

Aims of workshop

- **1.** Work through a basic data analysis in R.
- 2. Understand how to import data from a CSV file into an R data frame.
- **3.** Use standard tools to summarize & manipulate data frames.
- 4. Learn how to install & use R packages.
- **5.** Use ggplot2 to create plots from data frames.
- 6. Learn through "live coding"—this includes learning from our mistakes!

Our goal: Analyze Divvy data from 2016 & 2017

- Investigate bike sharing trends in Chicago.
- We will use data made available from Divvy:
 - www.divvybikes.com/system-data
- Much of the effort will be spent importing the data, inspecting the data, and preparing the data for analysis.
- Once we have carefully prepared the data, creating visualizations is (relatively) easy.

It's your choice

Your may choose to...

- Use R on your laptop.
- Use RStudio on your laptop.
- Use R or RStudio on the RCC cluster.
- Pair up with your neighbour.
- Follow what I do on the projector.

Note: If you use the RCC cluster I'm assuming you know how to set up an interactive computing session with appropriate amount of compute time and memory, load R or RStudio, and display graphics (e.g., using ThinLinc).

Software we will use today

- 1. R
- 2. R packages readr, ggplot2 & cowplot.
- 3. RStudio (optional).

Note: I'm assuming you have already installed R and/or RStudio on your laptop, or you are using the RCC cluster.

Outline of workshop

- 1. Initial setup.
- 2. Load & prepare the Divvy station data.
- 3. Load & prepare the Divvy trip data.
- 4. Create a map of the Divvy stations.
- **5.** Create plots comparing bike sharing in 2016 & 2017.

Initial setup

- WiFi
- Power outlets
- Pace, questions (e.g., keyboard shortcuts).
- Help.

Download or "clone" git repository

Download the workshop packet to your computer.

- Go to: github.com/rcc-uchicago/R-intro-divvy
- To download, click the green "Clone or download" button.

Or, if you have git, run this command:

```
git clone https://github.com/rcc-uchicago/
R-intro-divvy.git
```

(Note the URL in the git command should not contain any spaces.)

• **Note:** If you are using the RCC cluster, also download workshop packet on the cluster.

What's in the workshop packet

- analysis: directory where the code and data for our analyses will be stored.
- **2. slides.pdf**: the workshop slides.

Open slides.pdf on your computer

- This PDF is useful for copying & pasting code from the slides.
- Note: sometimes copying multi-line code doesn't work.)
- The PDF is included in the workshop packet.
- You can also view the PDF by clicking the "slides.pdf" item on the GitHub webpage.

Set up your R environment

- Launch R or RStudio.
- We will run all the code from the "analysis" folder.
- To change your working directory:
 - ▷ In R, use setwd() function.
 - ▷ In RStudio, select Session > Set Working Directory > Choose Directory…

Before continuing, check that you have the right working directory:

```
getwd() # Should end with "analysis".
```

Run sessionInfo()

Check the version of R that you are using:

```
sessionInfo()
```

If you are using an older version of R (version 3.3 or less), I strongly recommend upgrading to the latest version. *Some of the examples may not work in older versions of R.*

Check your R environment

The R environment is where all variables and functions are stored and accessed. You should start with an empty environment:

```
ls()
```

If you see names of objects listed, it means your environment is not empty, and you should restart R with a clean environment.

- Do rm(list = ls()).
- Or, in RStudio, go to Session > Restart R.

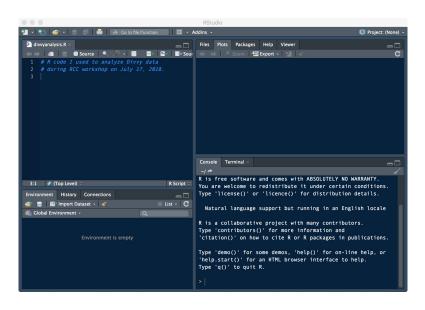

Create a file to keep track of your analysis code

- In RStudio, select File > R Script.
- Alternatively, use your favourite editor.
- Add some comments to the title to remind yourself what this file is for, e.g.,

```
# Some of the R code I wrote during the RCC # workshop on August 16, 2018.
```

 Save the file in the "analysis" folder. Name the file whatever you'd like (e.g., divvyanalysis.R).

The Console is the "brains" of RStudio

Download the Divvy data

- Disk space required: at least 2 GB.
- Download the 2016 & 2017 data files from here:
- Download them to the "analysis" folder.
- You should have 4 ZIP files:

```
Divvy_Trips_2016_Q1Q2.zip
Divvy_Trips_2016_Q3Q4.zip
Divvy_Trips_2017_Q1Q2.zip
Divvy_Trips_2017_Q3Q4.zip
```

Decompress ("unzip") all of these files.

Check that you have all the files

After unzipping, you should have 15 CSV files.

```
Sys.glob("*.csv")
```

If you don't see all 15 CSV files, you have not successfully downloaded and/or unzipped all the files in the "data" directory.

Outline of workshop

- 1. Initial setup.
- 2. Load & prepare the Divvy station data.
- 3. Load & prepare the Divvy trip data.
- 4. Create a map of the Divvy stations.
- **5.** Create plots comparing bike sharing in 2016 & 2017.

Eyeball the station data in the CSV file

- Open the CSV file Divvy_Stations_2017_Q1Q2.csv in RStudio, or in your favourite text editor (e.g., Notepad in Windows, TextEdit on Mac).
- CSV is a simple and commonly used data format.
- It is easily read into R, and read by humans.
- Each line stores an item (station).
- The first line is a special line called the "header".
- Entries in each line (table row) are separated by commas.

Import the station data into R

Load the most up-to-date station data into an R "data frame":

```
stations <- read.csv("Divvy_Stations_2017_Q3Q4.csv" stringsAsFactors = FALSE)
```

This will define a new object, "stations", in your environment:

```
ls()
```

It is a "data frame" object:

```
class(stations)
```

What does "read.csv" do, and what is a "data frame"? R has detailed documentation:

```
help(read.csv)
help(data.frame)
```

Inspect the station data

Run these commands to start inspecting the station data:

```
nrow(stations)
ncol(stations)
head(stations)
tail(stations)
summary(stations)
```

Inspect the data in more detail:

```
sapply(stations, class)
object.size(stations)
```

What do we learn about the station data from running these commands? Does this reveal any issues with the data?

Take a closer look at the "dpcapacity" column

Create a new object containing only the "dpcapacity" column:

```
x <- stations$dpcapacity
```

Run these commands to take a closer look at the "dpcapacity" column:

```
class(x)
length(x)
summary(x)
table(x)
```

Did we gain any additional insight from running these commands?

Take an even closer look at "dpcapacity"

It is interesting that a few of the Divvy bike stations are much larger than the others, whereas others have no docks. Where are these stations?

```
subset (stations, dpcapacity == 0)
subset (stations, dpcapacity >= 40)
```

Alternatively, we can sort the table rows, then inspect the top and bottom rows:

```
rows <- order(stations$dpcapacity, decreasing=TRUE)
stations2 <- stations[rows,]
head(stations2)
tail(stations2)</pre>
```

How were the rows originally ordered in stations?

Take a closer look at the "city" column

Above we inspected *numeric* data. Next's, let's look at an example of non-numeric data.

```
x <- stations$city
class(x)
summary(x)</pre>
```

The summary is not very useful here! The key is to convert to a "factor" (categorical variable):

```
x <- factor(stations$city)
class(x)
summary(x)</pre>
```

Did you discover an issue with the data from running these commands?

What is a "factor"?

TO DO: Add more text to this slide.

Factors are often very useful in data analyses. Let's take a deeper look.

```
attributes(x)
unclass(x)
```

From the unclass(x) call, we see that a factor is really just an integer with values 1, 2, 3, *etc.*, with which each integer value is associated with a *label* (e.g., "Chicago", "Evanston").

Improving the "city" column

Let's fix the problem we found earlier. First, select the offending rows of the table:

```
rows <- which (stations $city == "Chicago")
```

Fix the "city" column by overwriting the "city" entries in the selected rows:

```
stations[rows,"city"] <- "Chicago"</pre>
```

The "city" column is more useful if it is a factor, so let's convert it:

```
summary(stations)
stations$city <- factor(stations$city)
summary(stations)</pre>
```

There are many ways to select rows & columns

Select first 4 rows of "name" column:

```
stations$name[1:4]
stations[1:4,2]
stations[1:4,"name"]
```

Do you prefer one of these approaches?

Select first 4 rows and multiple columns:

```
stations[1:4,c(2,3,6)]
stations[1:4,c("name","city","dpcapacity")]
```

Can rows be selected by name?

```
colnames (stations)
rownames (stations)
```

Save your code & session state

It is important to periodically save:

- 1. your code,
- 2. the state of your R environment.

To save your environment, go to **Session > Save Workspace As...** in RStudio, or run this code:

```
save.image("divvyanalysis.RData")
```

Later, to restore your environment in a new session, select **Session > Load Workspace...** in RStudio, or run this code:

```
load("divvyanalysis.RData")
```

Main concepts covered so far

- The R environment & working directory.
- Read a data frame from a text (CSV) file.
- Tools to inspect a data frame.
- Manipulate a data frame.
- Factors = categorical variables.
- Selecting & and columns.
- Order rows of a data frame.
- Save state of R environment.

Outline of workshop

- 1. Initial setup.
- 2. Load and prepare the Divvy station data.
- 3. Load and prepare the Divvy trip data.
- **4.** Create a map of the Divvy stations.
- **5.** Create a scatterplot comparing bike sharing activity in 2016 and 2017.

Import the Divvy trip data into R

Previously, we used read.csv to import station data into R. Let's now use read.csv to load the trip data from the 4th quarter of 2017:

You may find that this command look longer to run than before. Consider that the trips data is much larger:

```
nrow(trips)
ncol(trips)
```

This gives an opportunity to demonstrate a faster method implemented in a *package*.

Import Divvy trip data using readr (optional)

Install the **readr** package from CRAN:

```
install.packages("readr")
```

Load the functions from the package into your R environment:

```
library(readr)
```

Let's use the read_csv function from this package:

```
trips <-
  read_csv("Divvy_Trips_2017_Q4.csv",na = "")</pre>
```

Note: read_csv is similar to read.csv, but not the same (I set na = "" to make read_csv more similar to read.csv).

How much faster is read_csv?

Import Divvy trip data using readr (optional)

The read_csv output is not a data frame—it is a "tibble".

```
class(trips)
```

Typically, I convert it to a data frame:

```
class(trips) <- "data.frame"</pre>
```

• For more on tibbles, see:

```
> http://r4ds.had.co.nz
```

- The readr package has many other features not covered here.
- Another fast method is fread from the data.table package.

More on packages in R

"Vignettes" are a great way to learn about a package:

```
vignette(package = "readr")
vignette("readr")
```

CRAN is the official package source:

```
    https://cran.r-project.org.
```

- Other good places to find packages:
 - ⊳ Bioconductor
 - GitHub.
- What packages are already installed?
 rownames (installed.packages ())
- Where do the packages live? .libPaths()
- How to learn more about a package?
 help (package=readr)

A first glance at the trips data

Let's use some of the same commands we used earlier to quickly get an overview of the trip data:

```
nrow(trips)
ncol(trips)
head(trips)
summary(trips)
```

Unfortunately, the summary command isn't particularly informative for many of the columns.

What columns should we convert to factors?

Convert "gender" to a factor

Let's start by converting the "gender" column to a factor:

```
trips$gender <- factor(trips$gender)
summary(trips$gender)
levels(trips$gender)</pre>
```

What problem have we stumbled upon?

Handling "missing" data

In R, "missing data" should always be assigned the special value ${\tt NA}$ ("not available" or "not assigned"):

```
rows <- which(trips$gender == "")
trips[rows,"gender"] <- NA
trips$gender <- factor(trips$gender)
summary(trips$gender)</pre>
```

Many functions in R will correctly handle missing data as long as they are encoded as ${\tt NA}.$

Convert "station" columns to factors

Next, let's convert the "from station" and "to station" columns to factors:

```
trips$from_station_name <-
  factor(trips$from_station_name)
trips$to_station_name <-
  factor(trips$to_station_name)
summary(trips)</pre>
```

The summary is now more informative.

A note about dates & times

- summary (trips) is also not useful for the dates & times.
- Processing dates & times is more complicated.
- See help(strptime) and the lubridate package.

Main concepts covered in second part

- Install & use a package.
- Handle missing data (NA's).
- Create a data frame.
- Create a plot from a data frame.

Preparing data is tedious

Data preparation is sometimes >90% of the effort!

• Many analysis mistakes are due to poor data preparation.

Common issues include:

- Formatting mistakes in CSV file.
- Converting table columns to the appropriate data type.
- Entry inconsistencies (e.g., additional spaces).
- Missing data.
- Many other examples of Poor Practices in recording data.

(And we haven't yet dealt with merging data from multiple files—this usually creates more headaches!)

Moving beyond data preparation

- So far, we have illustrated a few of the challenges of working with large tabular data sets ("data frames").
- In order to proceed to fun stuff, I've "hidden" some of the additional complications—I wrote a function in R to import and merge all the Divvy data into a single data frame.

Outline of workshop

- 1. Initial setup.
- 2. Load & prepare the Divvy station data.
- 3. Load & prepare the Divvy trip data.
- 4. Create a map of the Divvy stations.
- **5.** Create plots comparing bike sharing in 2016 & 2017.

- So far, we have only analyzed the trip data from the 4th quarter of 2017.
- I wrote a function read.divvy.data to automate the reading and processing of all the downloaded Divvy data: it reads all the CSV files, then merge them into two data frames: one for the stations, and one for the trips. Run this code to load this function into your R environment:

```
source("functions.R")
```

Choose which station and trip files to import:

```
tripfiles <- Sys.glob("Divvy_Trips*.csv")
stnfile <- "Divvy_Stations_2017_Q3Q4.csv"</pre>
```

Variables stnfile and tripfiles contains the names of the files to be imported they do not actually contain any data. **Note:** If your computer does not have enough memory to load all the trip data, run this instead:

```
tripfiles <- Sys.glob("Divvy_Trips*Q1.csv")`</pre>
```

This may take a minute to run, or longer if you have not installed the readr package.

```
divvy <- read.divvy.data(stnfile,tripfiles)</pre>
```

What read.divvy.data does:

- Reads the Divvy station data from the specified CSV file.
- Reads the Divvy trip data from the specified CSV files.
- Combines the Divvy trip data into a single data frame.
- Takes additional steps to prepare the data for a more convenient analysis; e.g., converts some columns to factors, extracts years from the "start time" column.
- Outputs a list object containing two data frames: (1) station data, (2) trip data.

The output is a "list" containing two data frames:

```
names(divvy)
stations <- divvy$stations
trips <- divvy$trips
rm(divvy)
head(stations)
head(trips)
nrow(trips)
object.size(trips)</pre>
```

- Were more trips taken in 2016 or 2017?
- Which columns were converted to factors?

Out first ggplot: a map of the Divvy stations

We will use the **ggplot2** package. It is a powerful (though not always intuitive) set of plotting functions that extend the base plotting fuctions in R.

```
install.packages("ggplot2")
```

I also recommend the **cowplot** package, an extension to ggplot2 developed by Claus Wilke at UT Austin.

```
install.packages("cowplot")
```

Load the ggplot2 and cowplot functions:

```
library(ggplot2)
library(cowplot)
```

Plot station longitude vs. latitude

The "stations" data frame gives the geographic co-ordinates (latitude & longitude) for each station. With ggplot, we can create a station map from the "stations" data frame in only a few lines of code:

Adjusting the plot

Let's make a few small adjustments to improve the plot:

What geographic features of Chicago are recognizable from this plot?

Scale stations by the number of departures

Next, let's add an additional piece of information to this visualization:

• Number of departures at each station, should (?) roughly correspond to population density.

To do this, we need to add a new column to the "stations" data frame containing the total number departures, which is calculated from the "trips" data frame:

```
counts <- table(trips$from_station_id)</pre>
```

The counts should be the same order as the stations—why is this?

```
all(names(counts) == stations$id)
```

Scale stations by the number of departures

Add these trip counts to the "stations" data frame:

```
stations$departures <- c(counts)
head(stations)</pre>
```

Let's use this column in our new plot:

How to save and share your plot

For exploratory analyses, GIF and PNG are great formats because the files are easy to attach to emails or webpages:

```
ggsave("station_map.png",
    plot = p,dpi = 150)
```

For print or publication, save in a vector graphics format:

```
ggsave("station_map.pdf",plot = p)
```

Save your code & session state

This is a good time to save your session.

```
save.image("divvyanalysis.RData")
```

Compare 2017 biking activity against 2016

Earlier, we observed an increase in trips from 2016 to 2017. Which stations experienced the largest increase?

- To examine this, we need to count trips separately for 2016 and 2017.
- Then we add these counts to the "stations" data frame.

We will use the subset and table to do this:

```
d1 <- subset(trips, start.year == 2016)
d2 <- subset(trips, start.year == 2017)
x1 <- table(d1$from_station_id)
x2 <- table(d2$from_station_id)
stations$dep.2016 <- c(x1)
stations$dep.2017 <- c(x2)
head(stations)</pre>
```

Scatterplot of trips by station (2016 vs. 2017)

As before, now that we have prepared a data frame, plotting with ggplot is relatively straightforward:

It is difficult to tell which stations had more trips in 2017—we need to compare against the x = y line.

One station stands out because it has had a much larger

Save your code & session state

Save your final results for safekeeping.

```
save.image("divvyanalysis.RData")
```

ggplot: Take home points

- Creating sophisticated plots requires relatively little effort provided the data are in the right form.
- All plots in ggplot have these three elements:
 - 1. A data frame.
 - 2. An "aesthetic mapping" that declares how columns are plotted.
 - **3.** A "geom", short for "geometric object," that specifies the type of plot.
- Plots are created by combining "layers" using the + operator.

Why data analysis in R?

- In R, a spreadsheet ("data frame") is an object that can be inspected, manipulated and summarized with code.
- Therefore, we can write scripts to automate our data analyses.

Parting thoughts

- 1. Always record your analysis steps in a file so you can reproduce them later.
- 2. Keep track of which packages (and the versions) you used with sessionInfo().
- 3. Use packages—don't reinvent the wheel.
- **4.** Email help@rcc.uchicago.edu for advice on using R on the RCC cluster.
- **5.** Use "R Markdown" to document your analyses.
- See the workflowr package for simplifying organizing & sharing of data analyses; e.g., stephenslab.github.io/wflow-divvy.
- 7. Thank you!
